Foreword to the First Edition

> I tell you what follows because *The Deep Sky Field Guide to Uranometria 2000.0* is one of those rare frontier-busting events that will permanently alter the course of amateur astronomy. This is not a catalog in the 19th century sense. It is more like a data file of easy access. It is not built for the coffee table but to augment another frontier buster—*Uranometria 2000.0*.

There are great moments in astronomy when barred doors open and unassailable frontiers crumble so that humans can swarm into the unknown, or so that is what we like to think. Actually, these great historical breakthroughs usually get treated in one of a number of interesting (meaning human) ways.

The new experience, the new knowledge, simply gets ignored, and when historians a century later write up the event, they never mention the indifferent response. Or, if the public is receptive, the new knowledge is embraced, raised to mythic status, and few young seekers dare raise questions or do more frontier-busting. Newton did such a good job on gravity that for a couple of centuries no more work was done. Newton was the giant oak whose biochemistry killed off all the sproutings of bay oaks around his "turf."

But, more often than the public realizes, the new exposure leads to major conflict (in some cultures, bloody ones). When Alvarez, a Nobel winner in physics, ventured his asteroid to explain the great slaughter of species, the astronomers sat back to see the fun. The geologists fought with each other, and in some cases professors were fired merely for having the wrong departmental opinion.

Of course, other "frontier busters" came up with something that had obvious and immediate value and fared better. Foucault's silver-on-glass mirrors almost doubled the light grasp of a reflector. And most importantly, re-silvering did not change the figure of the mirror like re-polishing a metal speculum always did. Immediately, silvering took over the field.

What can we expect from the DSFG and its twin, *Uranometria 2000.0*? For one thing the constellations, useful as they were to goat herders 5000 years ago and despite the cultural job they provide for historians, are nothing but obstacles to today's fast-lane observers. The *Uranometria 2000.0* map number is now the key to the data.

With the book you are now holding in your hands and *Uranometria 2000.0*, you are about to experience the joy of having a map to 9.5 magnitude *and* the nonstellar tabular data for just that map. The working package is now *map + guide* and a *telescope*. That is all you need to begin your assault. And if a nova or comet intrudes on your dreams you can check immediately, no running back to the house to find the right catalog. This bridge, this union, will come from this symbiosis of *map-guide-telescope-observer.*

And what about the future? Add a few of the very talented, the "frontier busters" of which James Lucyk, Murray Cragin, and Barry Rappaport are current examples, and the next generation of amateur astronomers will excel and exceed anything we plan and write today. I can hardly wait.

This book is a classic before it even goes through the literary Foucault test.

WALTER SCOTT HOUSTON

Introduction

What is the *Deep Sky Field Guide* (DSFG)?

To describe the DSFG, we must first introduce *Uranometria 2000.0 Deep Sky Atlas*, the "Second Edition" of *Uranometria 2000.0*, which was first published in 1987. With the rise in popularity and availability of large amateur telescopes and sophisticated CCD cameras, the number of nonstellar deep-sky objects available to amateur observers has increased dramatically. This new version of *Uranometria 2000.0* reflects this increase by plotting more than 30,000 nonstellar deep-sky objects—a considerable increase over the first edition. Although all of these objects are named and their symbols reflect their object type on the *Uranometria* charts, and while many are plotted to reflect their actual size, little else about them can be discerned merely from their chart symbols. This is where the DSFG comes in.

The purpose of the DSFG is to provide basic catalog data for each of the more than 30,000 nonstellar objects plotted on the 220 *Uranometria 2000.0 Deep Sky Atlas* charts. This catalog data is that information which would be most useful to telescopic observers using any aperture, as well as astrophotographers and CCD imagers. Basic data includes each object's coordinates, brightness, and size. Also provided is information specific to the type of object being observed or imaged, such as alternate names, number of stars, position angle, opacity, and so on.

While readers familiar with the first edition of the DSFG will see a familiar format, there are many changes and improvements in this edition, not only in the data provided, but in how it was created. To better understand this creative process, we first need to offer a short history of modern astronomical cataloging.

The modern era of cataloging began in 1958 with the completion of The National Geographic Society–Palomar Observatory Sky Survey (POSS) which was a photographic survey of the northern hemisphere night sky taken with the 48-inch Oschin Schmidt Telescope on Palomar Mountain. The southern hemisphere was later photographed in 1975–82 using the UK 1.2-meter Schmidt Telescope at Siding Spring Observatory in Australia. While they both extend beyond the Celestial Equator, only when they are combined do we get a high-quality photographic record of the entire sky from pole to pole.

Until recently, catalogs based on these surveys were created by taking visual measurements from the photographic plates, and compiling the data by hand. This methodology made these early catalogs highly prone to human error, both in measurement and transcription. Moreover, subsequent works took this earlier data at face value, thus propagating those errors through many years and many catalogs. If a newer catalog does make a legitimate correction, it may be deemed erroneous because it does not agree with the majority of other (incorrect) ones!

Starting in the 1980s, both the POSS and the UK Schmidt Telescope Surveys were digitized (the photographic plates were scanned and converted to computer-readable files) by the Space Telescope Science Institute as part of an eight-year effort to support the Hubble Space Telescope. By the mid-1990s, this data, now called the *Digitized Sky Survey* (DSS), was compressed and made available to the general public for download via the Internet. With the availability of the DSS to anyone with a computer, it was possible to access DSS images and verify catalog data against the original source—the sky itself! However, manually downloading and inspecting images from a very large list of objects would be a daunting task, and corrections would still have to be transcribed by hand—a process both time-consuming and open to human error. What was needed was a way to more or less automate the process of inspecting DSS images and recording corrections.

The solution used in the creation of *Uranometria 2000.0 Deep Sky Atlas*, and its companion *Deep Sky Field Guide*, was provided by Emil Bonanno in the form of a highly modified version of his commercial computer program *Megastar: A Sky Atlas for Windows*. Normally this program allows a user to replace the program's artificial sky with registered images from the DSS, and overlay these images with symbols from the stellar and nonstellar databases. This allows a user not only to see the real stars, galaxies, clusters, and nebulae of the actual sky, but to see where the various catalogs place these objects relative to their true positions.

The standard program was then modified to add tools that allowed the user to move the nonstellar deep-sky object symbols, as well as to change their sizes and orientations (such as position angle for galaxies). There were special tools for use with galaxies, clusters and planetary nebulae. The end result was, where a specific nonstellar object's catalog symbol did not fall precisely on its DSS image, its symbol could be moved to the proper position. Then any changes made in an object's placement, size, orientation, etc., were automatically transferred to the DSFG/

Uranometria 2000.0 database. In addition, provisions were made that enabled the user to manually enter notes for each nonstellar object if desired—notes such as the distance and direction to nearby bright stars or nonstellar objects not plotted on the charts. Co-author Murray Cragin then spent the next two years going through the entire nonstellar database several times, refining the data as required, and adding notes.

Since the DSFG is primarily a field guide, and its information is targeted toward visual, photographic and CCD observers, other astrophysical information has been omitted, such as the absolute magnitude of clusters or the radial velocities of galaxies (things not truly needed at the telescope). And because it is possible to determine positions directly from the DSS with a high degree of accuracy, for this edition of the DSFG we have chosen to provide coordinates in the more precise format of HH MM SS.d and +/– DD MM SS. Hopefully users of digital setting circles and computer-controlled telescopes will find this increased accuracy useful, particularly in crowded fields. We believe that these positions are quite accurate for galaxies, planetary nebulae and globular clusters. For larger, less well-defined objects such as open clusters and nebulae, one should not infer that we have determined the center of mass by anything other than visual inspection of the DSS.

In the notes, stars are often referenced, giving their distance and direction, to help aid observers in finding particularly elusive objects. Two stellar databases were used for these notes, the *Guide Star Catalog* (GSC—a companion project of the DSS) and the *Hipparcos/Tycho* star catalogs. When available, the more accurate *Hipparchos/Tycho* data was used. In the latter, star brightnesses are expressed as visual (V) magnitudes and have *two* places to the right of the decimal (e.g., mag 8.34v), while the *Guide Star Catalog* magnitudes are photographic and have only *one* place to the right of the decimal (e.g., mag 13.4).

The selection of nonstellar deep-sky objects for inclusion in this edition of *Uranometria 2000.0* and the DSFG was made so as to provide a much more complete catalog than the original. Galaxies were chosen based on an approximate magnitude cutoff of 15(B) and a major axis of at least 1.5 arcminutes, with exceptions being made on an individual basis. However, all NGCs were included regardless of magnitude or size. In addition, over 1,100 planetary nebulae are plotted. The open clusters are a 1,617-object subset of a catalog prepared by Brent Archinal, comprising objects which are clearly visible on the DSS, and likely to be visible with amateur instruments. And new to this edition, we have added all confirmable dark nebulae from Barnard's *Atlas of Selected Regions of the Milky Way, Part II: Charts and Tables*. The list goes on as you will see in the sections that follow. While we may not have included everyone's favorite "challenge object," we do provide a greatly expanded database, with a much higher degree of accuracy, that should push the envelope for all observers.

What follows is a general outline of the information collected here: the sources, the uncertainties, and how the various data is relevant to observing. Insofar as possible, the best and most recent deep-sky data has been used, with many changes and additions having been made in the last months before publication based on new findings from the professional community. Some idea of the array of information collected here can be obtained by scanning the bibliography at the end of this Introduction.

The Data

Overall Arrangement

The *Deep Sky Field Guide* presents data as 220 tables—it is, fundamentally, 220 mini-catalogs, one table for each *Uranometria 2000.0* double-page chart. Each table is headed on either side by large bold numbers that correspond to its atlas chart number. Within each table, deep-sky objects are grouped into separate sections by type, starting with galaxies, then galaxy clusters, open clusters, globular clusters, bright nebulae, dark nebulae and finally planetary nebulae. Other objects—quasars, radio and X-ray sources, variable and double stars—although charted in the atlas, are not included in DSFG. Within each section of a table individual objects are listed in alphabetical order by catalog prefix (Be, IC, NGC, etc.), and ordered numerically within each prefix group. This is another break from conventional catalogs where objects are arranged in Right Ascension order. We have found that in these more compact tables, it is much easier to use names rather than the coordinates. Also, three Indexes—Messier Objects, Name, and Alternate Name—are provided to enable rapid location of an object by chart-table.

Uranometria 2000.0 "outlying objects"

A quick look at the pages of *Uranometria 2000.0* shows that many large nonstellar objects span one or more charts. For example, NGC 224 (M31) appears on Chart 30; but part of this large galaxy can also be found on adjoining Charts 44, 45 and 62. In addition to extended objects, such as the larger dark and bright nebulae, there are instances where smaller objects fall on, or partially on, the RA or Declination lines bridging two adjoining maps, with the majority of the object falling outside the chart's boundary lines (see MCG +3-59-47 in the upper right corner of Chart 81, or NGC 4556 and 4558 at Chart 71's right margin). We call these *outlying objects*. And as the numbers of these outlying objects began to add up, it became quickly apparent that to avoid costly duplication of data, and more bulk to an already large book, a decision had to be made as to when to include data for an outlying object in a table, or leave it off and let the adjoining chart's table pick it up. Our answer became the "51% rule." If 51% of an object lay within the boundary lines of a chart, data for the object was included in that chart's DSFG table. If less than 51% of the object fell within a chart, its data will be found in the table for the chart that holds the majority of the object. In the case of NGC 224 (M31) above, its index listing shows only Chart 30, so only table 30 lists this object with its data.

Thus, if you find an object only partially inside the boundary lines of a chart, and there is no line of data for it in the corresponding DSFG table, then look for it in the adjoining chart's table.

Galaxies

The DSFG contains 25,895 galaxies. These objects are complete star systems like our own Milky Way Galaxy. A typical galaxy is composed of billions of stars, while the largest can easily exceed a trillion stars. For the most part, clusters and nebulae in other galaxies are well out of visual range. Amateurs equipped with large scopes will be able to observe detail in only a few hundred of the brightest examples.

As with any deep-sky object, the most basic question asked by the observer is: "Will this galaxy be visible in my telescope under my observing conditions?" The data presented here will help you answer that question and others. A key feature of the DSFG is the "Notes" section for each chart, which draws on visual examination of the DSS and a variety of other sources to expand on and complement the numerical data.

This work includes galaxies of magnitude 15 or brighter, or with a major axis of 1.5 arcminutes or larger. As noted before, all NGC objects are included regardless of magnitude or size. Positions, dimensions and position angles were confirmed, and modified where necessary, by visual inspection of Digitized Sky Survey images. There are undoubtedly still identification, position and general data problems in the resulting DSFG galaxy database, but we believe that the procedures we have followed have greatly reduced them.

Galaxy Classification

Introduction

The DSFG provides type-classifications for almost all of its galaxies. The majority of these classifications come from the *Third Reference Catalogue of Bright Galazies* (RC3), and employ the "Revised Hubble" system that Gerard de Vaucouleurs developed and extended in the 1950s from Edwin Hubble's original system of the 1920s, and from Harlow Shapley's work during the 1930s. The Revised Hubble system is described by de Vaucouleurs in an article that appeared in *Handbuch der Physik* in 1958. Minor revisions to it were presented in the introductions to the three *Reference Catalogues of Bright Galaxies* (de Vaucouleurs and de Vaucouleurs 1964; de Vaucouleurs et al 1976; and de Vaucouleurs et al 1991). The Revised Hubble system is summarized in Table 1, adopted from RC3.

Most of the Revised Hubble types in RC3 come from the *Uppsala General Catalogue of Galaxies* (Nilson 1973), the *Southern Galaxy Catalogue* (Corwin et al 1985), the *ESO-Uppsala Survey of the ESO (B) Atlas* (Lauberts 1982), and the *South-Equatorial Galaxy Catalogue* (Corwin and Skiff 1999). Some of the Revised Hubble classifications in RC3 are transformed from the less widely used systems of Eric Holmberg (1958) and Sidney van den Bergh (1960).

Table 1
The Revised Morphological Galaxy Classification System

Classes	Families	Varieties	Stages	T	Type
Ellipticals		Compact		−6	cE
			Elliptical (0–6)	−5	E0
				−5	E0–1
		"cD"		−4	E+

			bc	4	Sbc
			c	5	Sc
			cd	6	Scd
			d	7	Sd
			dm	8	Sdm
			m	9	Sm
Irregulars	Non-barred				IA
	Barred				IB
	Mixed				IAB
		S-shaped			I(s)
			Non-Magellanic	90	I0
			Magellanic	10	Im
		Compact		11	cI
Peculiars				99	Pec
Peculiarities			Peculiarity		p
(All types)			Uncertain		:
			Doubtful		?
			Spindle		sp
			Outer ring		(R)
			Pseudo outer ring		(R')

Several hundred galaxies in the DSFG do not have classifications in RC3. Some of these have, however, been classified on the similar "Hubble-Sandage" system, Hubble's system as extended and revised by Allan Sandage, beginning in the 1950s. This system is fully described and beautifully illustrated in the *Carnegie Atlas of Galaxies* by Sandage and John Bedke (1994). The Hubble-Sandage system is summarized in Table 2.

Over much of their range, the two revised systems differ only in notation, so the galaxy types from either system can be used interchangeably for most objects. Both systems use terminology implying evolution: "early" type galaxies are dominated by central bulges composed of old, cool, red stars; while "late" types are dominated by extended disks of young, hot, blue stars. The terminology was introduced by Hubble as a shorthand to describe his sequence of galaxy types running from "elliptical" through "spiral" to "irregular." However, it has been clear for many years that no galaxy actually evolves along the Hubble sequence. The galaxy types are dependent on many factors including mass, rotation speed, and environment. The

Table 2
Coding for Hubble-Sandage Galaxy Classification

Classes	Sub-Classes		Other Elements	Type Codes
Ellipticals				E
Dwarf Ellipticals				d E
			Flattening	E(0–7)
				E/SO
(Transition)				SO(s)
SO	Normal	Normal		SB0
	Barred	Ringed		S0(r)
		Inner		RSO
		Outer		PSO
		Partial Outer		d SO
Dwarf SO				$SB0_{(1-3)}$
			Disk/Bar Strength	S0[(0)–(9)]
			Flattening	
				SO/a
(Transition)				S[a–d,m](s)
Spirals	Normal	Normal		SB[a–d, m]
	Barred	Ringed		S(r)
		Inner		RS
		Outer		PS
		Partial Outer		
Irregular	Normal			IM
	Barred			IBm
Blue Compact Dwarf				BCD
			Peculiarity	. . . pec
Amorphous				Amorphous
Merged				Merged
Tides				Tides
Jets				Jets
Peculiar				Peculiar

actual evolution of a single galaxy through its lifetime is thus so complex that it has not yet been fully worked out.

All of these now-traditional galaxy classifications come from photographic plates with peak spectral responses in the blue. These plates give prominence to galaxy disks that feature hot, young objects associated with star formation (O and B stars, HII regions, star clusters, and so on). Images taken with plates or detectors sensitive to longer wavelengths emphasize the cooler, older, redder stars that make up the bulges of galaxies. However, the largest amount of classification has been done on blue-sensitive plates, so virtually all of the galaxy types in the DSFG are derived from them.

Explanation of the Classification Symbols

Both systems have adopted notations based on seven classification elements of varying length, filled or not as possible (depending primarily on plate resolution), with letters, numbers, or other symbols. If a feature corresponding to one of the elements is present in a galaxy, the symbol describing that feature is written in a standard sequence. Elements missing from a particular galaxy are simply omitted, but the symbols are distinctive enough so that little confusion can arise. A "complete" classification might look like this in the Revised Hubble system: "(R)SB(s)a pec sp". In the Hubble-Sandage system, this would be expressed as "RSBa(s) pec".

Uncertainty symbols (":" and "?") were originally applied immediately following the symbols for the uncertain features. For example, if a bar was merely suspected in an edgewise galaxy, it would have been noted "SB?c". However, because limited character sets were available on early computers, classifications were further coded in the three Reference Catalogues (see the introductions to those catalogs for explanations of that coding). In that process, the uncertainty symbols were moved to the end of the coded classification. Since DSFG uses classifications decoded from RC3, the uncertainty symbols appear at the end of the classification rather than just after the symbol which is actually uncertain. Thus, an "SB?c" classification becomes "SBc?" in the DSFG.

In the following paragraphs, the notation used in the Revised Hubble (RH) system is described first (because most of the classifications in the DSFG are on this system), followed by additional explanation of the Hubble-Sandage (HS) system when needed.

- The first element is optional: if the galaxy has an outer ring, or a partial outer ring, it is noted as (R) or (R') by the RH system, and as R or PR by the HS. This element is also occasionally used to note a dwarf ("d") spheroidal galaxy in both classification systems, or a compact ("c") elliptical galaxy in the RH system. The RH system also uses "c" here for compact irregular galaxies, while the HS system codes these as "BCD" (blue compact dwarf).
- The second element codes the major class of the galaxy: "E" for elliptical; "S" for spiral or lenticular; "E/S" for a transition case; "Sph" for spheroidal (usually dwarf galaxies); "I" for irregular; and "P" for peculiar. Some classifiers use an "L" for the lenticular galaxies, but RC3 did not adopt this notation. The dwarf lenticular galaxies are called "dS0" in the HS system.
- The third element is the family: "A" for unbarred (or "ordinary"), "B" for barred, and "AB" for transition cases. The HS system omits the "A" completely; transition cases there are noted with a forward slash between two complete types. "Sa(s)/SBa(s)" is an example. For elliptical galaxies, this third element codes the flattening index, 10 x (a-b)/a, rounded to a single digit between 0 and 6 (0 and 7 in the HS system).
- The fourth element in the RH system labels the variety: "(r)" for ringed, "(s)" for S-shaped, and "(rs)" or "(sr)" for transition cases.
- The fifth element in the RH system codes the stage along the Hubble sequence with lower case letters: "a", "ab", "b", "bc", "c", "cd", "d", "dm", and "m". This element also uses "0" (zero) to distinguish the lenticular galaxies from the spirals. In the RH system, this "0" has a superscript minus sign, zero, or plus sign to indicate the stage within the lenticular class. The HS system adopts subscript numbers 1 to 3 for stages.
  The RH system also has an "0/a" designation for galaxies that bridge the transition between lenticular and spiral. The zero is also used with the irregular ("I") class to flag the amorphous, irregular systems like M82 and NGC 3077. (These galaxies are simply called "Amorphous" in the HS system).

The HS system interchanges the fourth and fifth elements of RH classifications, adopting the Hubble stage as the fourth element, and using the fifth one for the variety (ringed or non-ringed) codes described above.

- The sixth element is used in the RH system primarily for indicating minor peculiarities by "pec" or sometimes just "p". The HS system uses this element for the luminosity class (discussed below) for spiral galaxies, or for the flattening index (in parentheses) for lenticulars (e.g. "(8)").
- The seventh and final element, also optional, in the RH system flags, with "sp" for "spindle", galaxies edge-on or nearly edge-on to our line of sight. This element is used in the HS system for "pec" to indicate minor peculiarities.

Summary

Galaxies are classified by assigning them to one of several major classes: elliptical, lenticular, spiral, irregular, spheroidal, or peculiar. Ellipticals are pure bulge galaxies, characterized only by a flattening index that describes their apparent shape. Lenticulars, still dominated by bulges, begin to show features associated with rotating disks. Spirals, with bulge and disk combined in a single system, are assigned stages depending on how tightly wound the arms appear, how large the bulge in the center of the galaxy is in relation to the disk, and how many knots (HII regions, star clouds, superassociations, etc.) appear along the arms. Irregulars are either of the Magellanic type (pure disk galaxies, forming an extension of the spiral sequence), or are amorphous. Over 95% of the nearby galaxies that we see on the sky can be comfortably fit within one or another of the first four classes, but some defy easy morphological binning, so they are simply called peculiar. The spheroidals are virtually all dwarf galaxies similar to the Fornax and Sculptor systems discovered by Shapley in the late 1930s.

Bars can appear among the lenticular, spiral, and Magellanic irregular galaxies. Barred lenticulars and spirals are just as common as non-barred galaxies, while barred Magellanic irregulars are much more common than non-barred irregulars.

Outer rings are most common at the lenticular/spiral transition stage. They can be seen in the later lenticular stages, and in spiral stages up to "Sbc". Galaxies of later stages "Sc" through "Sm" almost never have outer rings; the few that do are very unusual, and are probably the result of mergers or collisions. Inner rings are also seen in the same range of lenticular and spiral stages, though they are occasionally present as far along as stage "Sd".

High-resolution images reveal other interesting features in the cores of galaxies. Many nearby objects are now known to have bars, rings, and spiral features contained entirely within the central part of the bulges that are usually overexposed on survey plates.

We now think that most of the major morphological features in galaxies are the result of 1) gravitational interactions among the myriad stars that comprise them; or 2) gravitational interactions among pairs or multiple galaxies. The diffusely-distributed gas and dust present in them interacts primarily through shock waves of various origins (supernovae, spiral density waves, magnetodynamics, random motions within spiral arms, etc.). These contribute the additional features associated with star formation (HII regions, star clusters and associations, etc.) seen in spiral and irregular galaxies. Interactions of gas and dust clouds, and the dynamically active cores of galaxies, are responsible for many of the interesting features currently found by extragalactic surveys in other parts of the spectrum (gamma ray, X-ray, ultraviolet, infrared, and radio).

Magnitudes

Visual magnitudes have been determined from data in the ESO-LV, RC3, or PGC in one of five ways:

- When the RC3 gives a total V magnitude instead of its more common total B magnitude, we adopted the V_T directly.
- When B_T and $(B-V)_T$ photoelectric data exists, a total V magnitude was calculated: $V_T = B_T - (B-V)_T$. This is the usual case for galaxies with photoelectric data, which number about 3,000.
- When B_T data is absent, a total V magnitude was calculated from m_B and $(B-V)_T$. These cases are rare.
- When $(B-V)_T$ is not known it was calculated from B_T with the following color estimates based on the galaxy's type (for T, see the preceding section on Galaxy Classification):

	(B – V)
$T \leq 0.0$	1.0
$0.0 < T \leq 2.0$	0.9
$2.0 < T \leq 4.0$	0.8
$4.0 < T \leq 6.0$	0.7
$6.0 < T \leq 7.5$	0.6
$7.5 < T \leq 11.0$	0.6
$T = 50$	0.8
T = not given	1.0

These cases are more common than the previous one, but still relatively rare.

- When neither B_T nor $(B-V)_T$ exists, a total V magnitude was calculated from m_B using the color estimates from the table above. This is the most common case.

Uncertainties in the total magnitudes range from only a few hundredths in the best instances with photoelectric and/or CCD data (the first and second cases above) to an upper limit of one-and-a-half magnitudes for values calculated by the last, rather indirect, method.

Dimensions

Galaxy dimensions cannot be easily measured. In practice, the *perceived* diameter is limited by the luminosity of the night sky, which is about magnitude 23.0 (B) per square arcsecond at a perfectly dark site. Some catalogs determine the extent of a galaxy by generating an isophote at some chosen surface brightness value (an isophote is a contour line tracing points of equal brightness around a galaxy). For example, the *RC3* uses 25.0 B-magnitudes per square arcsecond. For most observers, this results in a size which is considerably beyond the limits of visual perception, even in a large telescope under excellent sky conditions.

Most of the dimensions shown here have been obtained by visual inspection of the DSS, and therefore

may differ from those found in other catalogs and literature. But the sizes presented here, in our experience, provide a closer match to what is perceptible using amateur equipment (for both visual observation and imaging).

Surface Brightness (SB)

As a broad generalization, surface brightness is calculated by dividing a galaxy's magnitude by its area. More precisely, once the total V magnitude and dimensions are known, the mean surface brightness is computed as follows:

$$V'_{25} = V_T + \Delta V + 5\log D - 2.5\log\left(\frac{D}{d}\right) - 0.26$$

where

V_T = total V magnitude

$\Delta V = 0.25$ or 0.33 for cD or E type galaxies (T = –6 to 4),

$\Delta V = 0.13$ or 0.16 for S0$^-$, S0, S0$^+$ type galaxies (T = –3 to –1),

$\Delta V = 0.11$ for all other galaxy types (T ≥ 0),

D = major axis in arcminutes, and

d = minor axis in arcminutes.

The value of ΔV is dependent upon the morphology of the galaxy and the magnitude isophote to which the dimensions are measured. For about 30% of the galaxies in the DSFG, our measured dimensions match those of the RC3, which indicates an isophote of 25.0 mag/arcsec^2. For those galaxies, the lower ΔV values (0.25 and 0.13) were used in the surface brightness computation. For the remainder, it was determined that our average isophote was 24.5 for elliptical galaxies, 24.7 for S0 types, and 25.0 for spirals. This corresponds to ΔV values of 0.33, 0.16 and 0.11, respectively.

The total magnitude in combination with the surface brightness provides a better indication of the visibility of a galaxy than the magnitude alone. For example, UGC 1378 (Chart 2) has a surface brightness of 14.7, meaning that it will appear as if each square arcminute of its area is as bright as a 14.7 magnitude star. (Try defocusing a 14th magnitude star until it is an arcminute across to get an idea of how faint this is!). Therefore, this galaxy will be more difficult to observe than its total magnitude (V = 12.6) might indicate. Experience suggests that objects with surface brightnesses fainter than 14.5 will be difficult to detect no matter what the total magnitude is. The "average" galaxy has a surface brightness of about 13.5, while the highest surface brightness objects have values of 12.5 or brighter.

The examples of the Andromeda Galaxy and its companions (Chart 30) serve to show that surface brightness does not depend on total magnitude. The main galaxy, M31, is a naked-eye object but has a surface brightness of 13.5, typical of mid-stage spirals. The small companion, NGC 221 = M32, is nearly five magnitudes fainter overall yet is visible in handheld binoculars because its surface brightness, 12.5, is so high. The companion NGC 205, although about the same total magnitude as M32, is much more difficult to see at a mean surface brightness of 14.0. The more distant companions NGC 185 and NGC 147 have still lower surface brightnesses, and despite being among the brightest galaxies in the sky by total magnitude, are often elusive to those seeking them from light-polluted observing sites.

Finally, we recommend that the surface brightness values presented here be regarded as qualitative indicators of relative brightness. The RC3 cites an average error of 0.33 for its surface brightness values, and we believe that our average error is somewhat greater than that. We have not normalized the density of the DSS images to achieve uniform isophotal dimensions, and many of the magnitudes used are of an unknown type. But even assuming perfect data, there can be structural variations within the same morphological type which will affect the visibility of a particular galaxy.

Position Angles (PA)

Position angles (PA) are given for noticeably elongated galaxies and were obtained directly from a visual inspection of the DSS. Obviously, position angles do not apply to circular objects. These angles, expressed in degrees, are measured from north through east. A value of 0° implies a north-south elongation. A PA of 90° indicates an east-west elongation. After a further quarter-turn counterclockwise, the object is again orientated in a PA of 180° (equivalent to 0°) again in a north-south direction. All PAs for galaxies are referred to the first half of the circle, so they do not exceed 179°.

To measure the PA of a galaxy in your eyepiece, you must first determine north as precisely as possible. The best method of doing so, especially with telescopes on alt-azimuth mounts (Dobsonians, etc.), is to first determine west. This is easily done by centering a bright star in the eyepiece and removing all drives to the telescope so that the star drifts to the edge of the field. The point where the star *exits* the field is *west*. North will then be 90° *counterclockwise* from the west point (*clockwise* for refractors and Schmidt-Cassegrain telescopes with star diagonals).

Knowing the position angle of a galaxy with respect to others can obviously be very helpful in identifying it in a crowded field. In a similar way, determining the PA of elongation for an "unknown" galaxy aids in identifying it later through catalog descriptions or on sky survey photographs.

DDO Luminosity Class

The range of intrinsic brightness among spiral and irregular galaxies is greater than a factor of 100 (five magnitudes). In 1960 Sidney van den Bergh, then at the University of Toronto's David Dunlap Observatory (DDO), introduced *luminosity classes* for these galaxies. This classification scheme employs the same capital Roman numerals that are used for the stellar luminosity classes: class I spirals are the bright supergiants; luminosity class V are the faint dwarfs; and classes II, III, and IV are objects of intermediate brightness.

Table 3
Examples of the DDO Luminosity Classes

DDO Class	Name	Chart No.	Mag V	Dimen.	SB	Type
I	NGC 4565	71		15.8 × 2.1		SA(s)b? sp
I–II	NGC 4725	71		5.4 × 4.3		SAB(r)ab pec
II	NGC 5012	71		2.9 × 1.7		SAB(rs)c
II–III	NGC 4826	71		10.0 × 5.4		(R)SA(rs)ab
III	NGC 4793	71		2.8 × 1.5		SAB(rs)c
III–IV	NGC 4961	71		1.6 × 1.1		SB(s)cd
IV	NGC 4455	72		2.8 × 0.8		SB(s)d? sp
IV–V	NGC 4561	71		1.5 × 1.3		SB(rs)dm
V	UGC 7673	72		1.8 × 1.5		Im

Since the above luminosity classes are assigned on the strength of the spiral arm pattern, they cannot be applied to elliptical or lenticular galaxies. Spirals with strong, well-formed arms are assigned luminosity class I. Those with weak but still traceable arms are denominated class III, and those with little or no trace of spiral structure are called class V. In practice, a trained observer can evaluate a galaxy to within half a step on this scale, so the intermediate classes I–II, II–III, III–IV, and IV–V are used as well.

There is also a loose correlation between luminosity class and surface brightness: as luminosity class increases, so does surface brightness. Most class I spirals have high surface brightnesses, while those of most dwarf galaxies of class V are low. This fact led Harold Corwin to introduce luminosity classes V-VI and VI for the extremely low-surface-brightness dwarf galaxies being found on the high-contrast, deeply-exposed IIIa-J plates used for the *ESO/SERC Southern Sky Survey* and the *Second Palomar Observatory Sky Survey*. It is not yet known, however, if these new classes correlate with absolute magnitude as do the "traditional" DDO luminosity classes. In any case, it is very doubtful that any of these low surface brightness dwarf systems can be seen visually in even large telescopes. Their average surface brightnesses are below 16th magnitude per square arcminute.

Examples of galaxies of varying luminosity classes are given in Table 3, and all are found on adjoining charts. Examining each of the galaxies on this list should demonstrate to the observer the ease in seeing those of classes I and II, and the difficulty in seeing class IV-V and V objects under nearly identical conditions.

Notes

The galaxy notes will very often identify nearby field stars, to help pinpoint the position of elusive targets, or they might point to other nearby nonstellar objects not plotted on the charts, yet seen on DSS images. These non-plotted, nonstellar objects are usually far fainter than those in the normal database; call them "challenge objects" if you will. The nonstellar objects in the notes whose names are printed in bold type are not plotted on the charts (common names and Messier names excepted), nor do they have data in the tables; however, direction and distance to them is provided in the notes. Nonstellar objects whose names are in normal type are found on the charts and appear in the tables.

Galaxy Clusters

The DSFG contains 671 galaxy clusters derived from George Abell's 1958 catalog based upon photographs from Palomar Mountain. In 1980, Abell issued a revision to this catalog, and in 1984 he died while engaged on a southern extension of it using photographs taken at the Anglo-Australian Observatory. This work was expanded upon and subsequently completed in 1989 by Harold Corwin and Ronald Olowin. The tables provided the following data:

- Name. Objects from the 1958 catalog are designated with an "A", and those from the 1989 work are designated with an "AS" prefix.
- Magnitude of 10th brightest galaxy.
- Number of galaxies.
- Diameters. Those for "A" objects are taken directly from Abell's revised catalog (1980). Similar data was not available for the "AS" clusters so the diameters were estimated based upon the distance class. For all "A" catalog objects having the same distance class, mean diameters were computed, and those values were applied to the "AS" clusters. Therefore these dimensions are indicative only, not precisely measured.

Open Clusters

The DSFG contains 1,617 objects that have been classified as open clusters, including those in the Magellanic Clouds. As will be explained later, not all of these objects are true open clusters, which are relatively young star associations scattered throughout the disk of the Galaxy. A familiar example is the Pleiades, found on Chart 78. These objects are also known as Galactic clusters, since all but those nearest the Earth are found near the plane of our Galaxy (Chart 8 shows twenty-seven).

In the very youngest cases, the remnants of the gas from which they formed are visible as nebulae in the surrounding field. In fact, a small number (78) of open clusters share a single designation with their nebulae. An example is NGC 1962 on Chart 212, which is listed as both an open cluster and a bright nebula in the respective sections, has two separate symbols on the chart, and is listed twice in the Index.

The number of stars in these objects ranges from only a few to thousands. In appearance they vary from rich, compact, easily distinguished objects, to a few stars so loosely grouped that they are hardly discernible from the surrounding star field. Many of the latter require experimentation with different apertures and magnifications to be seen. Small telescope users will probably be able to view a larger percentage of open clusters than other types of deep-sky objects.

The principal source used for data on open clusters is the book *Star Clusters* by Brent Archinal and Steven Hynes, in press, to be published by Willmann-Bell. The DSFG employs a subset of that data which was determined

by a review of the entire catalog by direct inspection of the DSS images by Cragin. His criteria were general visibility and the likelihood that the object could be seen by amateurs. In addition to the cluster name, five other items of data are presented:

- Position. Archinal and Skiff directly inspected DSS images for each object taking as their starting position that specified in the primary source catalog. This work included, as necessary, identification of faint or sparse clusters or those with obviously wrong positions, using original source material. All positions are visual estimates from the DSS and are not based upon center-of-mass calculations. In all instances these should be sufficient for DSFG users to locate and identify the object.
- Integrated magnitude. Unless otherwise noted, these are V (visual) magnitudes. For Galactic objects, these values have generally been determined by Skiff, who summed the brightnesses of individual stars in clusters with published photometry. Their uncertainties are typically ±0.2 magnitude. A colon indicates a particularly uncertain value, nearly always a faint limit, due to there being photometry for only a handful of the cluster stars. Photographic blue magnitudes, coded with a "p" following the value, derive ultimately from Collinder's 1931 monograph on star clusters. A comparison with Skiff's magnitudes indicates the Collinder values are on average about half a magnitude fainter and scatter by one-half to two-thirds of a magnitude about the mean difference.

  For clusters with no magnitude determined by Skiff, earlier, much less accurate (usually photographically determined) magnitudes are given. These and other values given (from SIMBAD) should generally be assumed to be only rough values good to within 0.5 to 1.0 magnitude.

  In the Magellanic Clouds, V magnitudes have been determined via photoelectric photometry and are accurate to perhaps ±0.1.
- Diameter in arcminutes. Since these values for cluster diameters are usually approximate, and are derived from widely varying photographic materials, they should be considered rough estimations.
- An estimate of the star count within the cluster and magnitude of the brightest star. For most of the brighter objects, the star count is representative of what is visible in a modest aperture (~20 cm) telescope from a dark site. The value greatly underestimates the true population of the cluster except for the poorest ones. In other instances the count may just be the number of stars for which photometry or spectral types have been obtained.
- Type. True clusters are assemblages of stars that have a common ancestry as revealed by spectroscopy. Over time many objects cataloged as clusters have been proven to be just chance groupings or appearance groupings of unrelated stars. Many of these objects have NGC or IC designations and are well established in the literature. We have chosen to include them here. This column presents Archinal's findings as to the nature of these objects. See Table 4.

Table 4
Cluster Types

Type	Explanation
2 cl	Two open clusters ("Double Cluster".)
ass	Association (NGC 1869).
ast	Asterism (NGC 1869).
ast?	Probable asterism, but possibly a real cluster NGC 1802).
cl	Open cluster (NGC 1846).
cl?	Possible open cluster, not well differentiated from an asterism (NGC 2609).
cl??	Type unknown, but possibly an open cluster (NGC 7826).
clpn	Open cluster and planetary nebula (NGC 2818).
MW	Asterism, either a rich Milky Way star field or obvious patch of bright Milky Way (NGC 5045).
MWcl	MW type or possible real cluster (NGC 5120).
ptcl	A portion of a larger open cluster (NGC 1750 part of NGC 1746).

- Notes. These include descriptions based on a three-part system developed by Trumpler in 1930. The three elements are: relative degree of concentration and detachment from the surrounding field; range of brightness of the apparent members; and richness or population ("poor," less than 50 stars; "moderate," 50 to 100 stars; "rich," over 100 stars). Also included are comments provided by Archinal, denoted by (A), and Skiff (S), as a by-product of their efforts to locate and measure positions and sometimes sizes on the DSS. Their estimates of cluster diameters may not agree precisely with compiled catalog data because they are from a different source.

The degree of "detachment" will naturally depend on the density of the surrounding field. The visual impression can differ considerably from assessments made from sky survey photographs. It is not difficult to imagine, for instance, that the Hyades (Charts 78 and 97) would be practically invisible as a cluster were it situated along the Galactic plane in Cygnus. Observers will often have an easier time visually distinguishing an object from its field, compared to their professional counterparts examining a sky survey photograph, where a perfectly good open cluster can be utterly swamped by a dense field of background stars.

We have not seen the faintest star in any open cluster, so except for the most meager objects, the true range in brightness is always very wide. The brightness range is better defined in this classification system as the range of the brightest members and actually correlates with cluster *age*. Young clusters (less than a few tens of millions of years old) have steeply rising main sequences that are essentially vertical on the color-magnitude diagram. So the 10th brightest star, say, can be a couple of magnitudes fainter than the brightest. There will invariably be many more fainter stars than brighter ones, so the magnitude range will seem large. In an old cluster (over several hundred million years), there is usually a well-populated giant branch of about the same brightness as the brightest stars still on the main sequence. Thus, what one sees visually and photographically is a mass of similarly-bright stars,

and so the range of magnitudes seems small. Both young and old clusters, however, have very faint, low-mass stars 10 or 15 magnitudes fainter than the brightest, so the real range is always large. Nevertheless, this type of classification is useful for observers.

The "richness" element should be thought of as indicative of how many stars there are in the brightest few magnitudes of a cluster. In reality, few objects have less than 100 stars, provided that very faint members are taken into account.

Globular Clusters

The DSFG contains data on 170 globular clusters, including both Milky Way and Magellanic Cloud objects. While open clusters have irregular outlines, globulars are strongly circular, and their stars are usually much more numerous, and densely packed toward the center. They are among the oldest objects to be found in galaxies, with ages near 13 billion years. The number of stars comprising them can range from 10,000 to over 100,000. While open clusters are found strictly in the Galactic plane, globulars are grouped into two regions: around the "hub" at the center of our Milky Way, and in its extended Galactic halo. All are gravitationally bound to our Galaxy even though a few are twice as far from its center as the Magellanic Clouds! Globulars are most numerous in the direction of the Galactic center (Chart 146 shows 19 of them), although many of these are greatly dimmed by interstellar dust (the non-NGC globulars listed for Chart 145 are examples).

The globular cluster data presented in this work contains the following information:

- Positions. These are from the precise measures by Shawl and White. Magellanic Cloud cluster positions are from lists by Kontizas *et al*, Welch, and the Lauberts *ESO/Uppsala Survey of the ESO (B) Atlas*.
- Integrated V (visual) magnitudes. The compilation by Webbink is the source for these, except in the case of Magellanic Cloud objects, which come from van den Bergh's 1981 summary and the work of Bica et al.
- Diameters. Since these values—given in arcminutes—are usually approximate, and are derived from widely varying photographic materials, they should be considered rough estimations.
- Concentration class. Such groupings were first assigned by Shapley and Sawyer. They assigned globulars to 12 numerical classes based on decreasing central concentration, with a value of 1 denoting the highest stellar concentration toward the center, and 12, almost no central concentration. The latter variety appears similar to faint versions of the richest open clusters. NGC 2808, found on Chart 210, is an example of a high (1) concentration, while IC 1276 on Chart 126 has the lowest (12) concentration classification.

The Shapley-Sawyer concentration classes are correlated with central surface brightness. They are *not* generally indicative of how easily a cluster can be resolved at the eyepiece. This is instead dependent almost solely on the magnitude of the brightest cluster stars compared to the limiting magnitude of the telescope in use.

- Estimates of the V magnitude of the brightest cluster stars and the magnitude of the "horizontal branch or HB" of the cluster's color-magnitude diagram. These are useful for both visual and photographic observing. To resolve a cluster into even a few stars requires that your telescope be able to reach at least the brightest members. The Shapley-Sawyer concentration class may play a small role (but only the most concentrated clusters will be more difficult to resolve), and the visual magnitude limit must be beyond these brightest stars in any case. As one goes to fainter limits, more and more stars will become resolved. The number of stars per magnitude interval increases slowly at first in globulars but takes a sudden leap upward at the magnitude of the horizontal branch, where there are many stars at nearly the same brightness in the cluster. Visually, the cluster changes in appearance from being "partially resolved" to "well resolved" if you can see stars this faint in the telescope.

  Descriptive notes for LMC globulars are based on their appearance in the plates of the Hodge and Wright atlas.

Star Clouds

The DSFG includes 14 star clouds. These objects are composed of countless stars and often span vast stretches of the night sky. When viewed at low power the nebulosity is often overlaid with sparkling stars which often do not show up in photographs. Usually star clouds are so vast that they cannot be plotted on a large-scale atlas however Chart 164 plots 7: NGC 6360, 6415, 6421, 6437, 6455, 6476 and 6480. Another, M 24 on Chart 145 is a visually striking star cloud that contains a number of other observable objects. Because there are so few of these plotted objects we have not included them in the chart legend but have assigned a special symbol and annotated the name with "(star cloud)" to aid in their identification. The symbol sizing is the same as that used for open clusters.

Bright Nebulae

The DSFG includes 377 bright nebulae. These objects, also called diffuse or Galactic nebulae, occur in two main classes depending on their source of illumination: emission or reflection (although they occasionally are a combination of the two). Much less common is a third type of bright nebula, the supernova remnant (SNR).

Emission nebulae are clouds of dust and glowing hydrogen gas, sometimes referred to as H II ("H-two") regions. The atoms in the cloud are ionized by nearby hot stars, and when their excited electrons fall back to their previous energy state the process releases energy in the form of visible light. A well-known example is the Lagoon

Nebula, found on Charts 145 and 146. Since most of the light visible from emission objects comes from just the three lines produced by hydrogen (Hβ at 4861Å) and oxygen ([OIII] at 5007Å and 4959Å), the use of narrowband "nebula" filters can be helpful in viewing them.

Reflection nebulae have the same composition as emission objects but lack stars sufficiently hot to cause the gas comprising them to fluoresce; therefore, they shine merely by the dust in the nebulae scattering starlight (the gas does not actually reflect any light). Good examples are the nebulosities surrounding the Pleiades star cluster (Chart 78) and M78 in Orion (Chart 116). Because these objects scatter starlight of all colors, filters are not generally helpful in viewing them.

A supernova remnant is the remains of a catastrophic stellar explosion, wherein much of a star's material is ejected, often as a highly structured cloud. Examples are the Veil Nebula in Cygnus (Chart 47) and the Crab Nebula (M1) in Taurus (Chart 77). These objects have strong emission lines similar to H II regions, hence also benefit from the application of nebula filters.

For bright nebulae the following information is provided herein:

- Dimensions. These are given in arcminutes and were taken from photographs. They represent the size of the nebula's brightest parts. Nevertheless, observers will often find these values to be considerably larger than what they can detect visually, even from dark sites.
- Type. This is denoted by the letters E (emission), R (reflection), E+R, and SNR (supernova remnant). As just explained, this information is useful in deciding whether a filter will be helpful.
- Brightness. Objects are assigned to a brightness category, which is a numerical value describing an object's brightness on the POSS. An arbitrary scale was used by Beverly Lynds in her catalogue of northern nebulae and ranges from 1 to 6, where 1 is brightest and 6 is barely detectable. Brightness is almost always expressed as a range in the tables. Provided sufficient aperture is used under good skies, experience suggests most category 1 and 2 emission nebulae are within visual range. Category 3 objects will prove difficult, while those rated 4 and above are likely to be beyond visual range and thus candidates for photographers instead. When compared on this same scale, reflection nebulae are generally considered to be more difficult to observe visually. Blue light is scattered more than red light, so the reflection nebulae are more often than not comparatively blue in color. But the light is not concentrated in just a few emission lines, so filters do not help much.
- Nebular color This is presented as a numerical value from 1 to 4, again based on Lynds' system from her inspection of the blue- and red-sensitive POSS plates. It is usually expressed as a range where

1 = brightest on blue plates
2 = equally prominent on both blue and red plates
3 = brightest on red plates
4 = visible only on red plates.

Nearly all the class 1 objects are reflection nebulae, since the scattering process makes them slightly bluer than the hot, blue stars that illuminate them. A notable exception is IC 4606 on Chart 147, which surrounds Antares: although it is a "reflection" object, it scatters the light of a red supergiant star. Class 2 objects are a mixture of emission and reflection, or more commonly, are generally overexposed emission objects. Nearly all class 3 nebulae will be emission objects. Class 4 includes weak or obscured emission objects.

- Notes. This explanatory material is largely based on photographic appearances of objects on the POSS, and the *ESO/SERC Atlas* reproductions in the *Atlas of Galactic Nebulae* by Neckel and Vehrenberg.

Dark Nebulae

The DSFG contains 367 dark nebulae. These objects are composed of clouds of gas and dust grains sufficiently dense as to become opaque. They are detectable if positioned between the observer and a bright nebula or a very dense star field, against which they will be seen silhouetted. Observationally, dark nebulae are among the most difficult deep-sky objects. The Coalsack, near the Southern Cross (Charts 198 and 209), is an example clearly visible to the unaided eye because it happens to lie in front of the rich, starry background of the Milky Way. On the other hand, the well-known Horsehead Nebula (cataloged as Barnard 33 on Chart 116) is much more typical. It is a difficult object because of its small size and because it lies in front of a rather faint background object, emission nebula IC 434. In this case the resulting contrast between the dark nebula and background is very low, making it difficult to distinguish. Dark nebulae are usually seen best with wide-field, low-power eyepieces, which provide a large, bright surrounding field. While these objects emit no light of their own, nebular filters may help increase the contrast if the background is an emission nebula.

The dark nebulae are presented here with the following information:

- Dimensions. These are given in arcminutes and were derived from photographs. As with bright nebulae, many of these objects have indistinct boundaries, and therefore the values provided should be considered approximate.
- Contrast. This is measured on a numerical scale of 1 to 6, where a value of 1 indicates the object is barely darker than the surrounding background, while those rated at 6 are the blackest and the most easily visible. Lynds found that the values corresponded fairly well with the number of magnitudes of absorption of background starlight by the nebula, so that a contrast 6 object dims starlight by about six magnitudes.

- Notes. These are primarily based on Barnard's "Catalogue of 349 Dark Objects in the Sky," found in *A Photographic Atlas of Selected Regions of the Milky Way*. Barnard's descriptions have been used (when available) because he often cataloged and described small areas within much larger complexes, while the Lynds *Catalogue of Dark Nebulae* often groups many of these smaller areas into a single, larger object. Where an object has a Lynds (LDN) designation, we provide Barnard's more detailed description, if available.

Planetary Nebulae

The DSFG encompasses 1,144 planetary nebulae. These are shells of gas thrown off by stars having approximately the Sun's mass, that are nearing toward the end of their evolutionary cycle following the red-giant stage. The shell gradually expands, until after perhaps 100,000 years it becomes undetectably thin and all that remains is the central star. Some of the earliest such objects discovered (e.g., NGC 3242 on Chart 151, and NGC 6210 on Chart 68) were found by William Herschel, who noted the resemblance of their well-defined disks to those of planets, and gave them the name "planetary nebulae", but of course they have nothing to do with planets.

The brightest planetaries have a substantial disk, typically 30 arcseconds across, but the majority listed here are stellar (or nearly so) and can be identified at the eyepiece only with a nebula filter or direct-vision prism. Chart 164 lists over 100 such objects, hardly any of which are larger than a few arcseconds in diameter. A few of the oldest and nearest objects are so distended as to be practically invisible against the background sky. Between these two extremes, planetaries come in about as many shapes as there are objects, including the aptly-named Ring Nebula on Chart 49 and the complex southern object NGC 5189 on Chart 208.

In visible light, planetary nebulae shine predominantly at the two wavelengths emitted by doubly-ionized oxygen, denoted by the symbol [OIII]. Typically, 90% of the visually-detectable light comes from the [OIII] lines at 5007Å and 4959Å in the blue-green part of the spectrum. As a result, when an [OIII] filter is placed between the eye and the eyepiece, stars are dimmed by as much as three magnitudes (the night-sky light even more), while light from a planetary passes through virtually unchanged. By rapidly passing an [OIII] filter between the eye and eyepiece and out again while examining the field, a planetary will usually appear to "blink" as the stars are dimmed, and the nebula retains it brightness. There are a few planetaries that have weak [OIII] emission (a bright example is PN G64.7+5.0, Campbell's Hydrogen Star, on Chart 48), and these are best viewed either directly or with an Hβ filter, which passes the line that is brightest in these cases.

The planetary nebula data is based on a catalog prepared by Hynes (presented in his book *Planetary Nebulae*) and the *Strasbourg-ESO Catalogue of Galactic Planetary Nebulae* and contains the following information:

- Positions. These are taken from Gordon and Kapplan.
- Name. The original "PK" system is based on Galactic coordinates to whole degrees only and within each one-degree block planetary nebulae were assigned a serial number. Thus NGC 40 = PK 120+09 1 (no decimal) is in the Galactic longitude 120° block at +9° latitude, and is the first planetary cataloged in that block. Acker et al. decided that the general improvement in positions meant that it is was possible to assign a unique name based on Galactic coordinates if the positions were given to 0.1 degree precision. Thus PN G120.0+09.8 shows that the object is at 120.0° longitude and +9.8° latitude. Since the boxes are now only 6′ on a side they are small enough that every object can have a unique name and it is not anticipated that another naming scheme will be needed in the future. These names have been adopted by modern catalogers.
- Magnitudes. These are given in two columns: photographic-blue and visual. The visual magnitudes were computed and provided by Marling, who summed the brightness of the emission lines for each object and adjusted the resulting value to account for the sensitivity of the dark-adapted eye. The uncertainties are in the range of ±0.2 magnitude. These data are far superior to early photographic estimates in blue light, most of which date from the 1930s. Since the photographic-blue magnitude does not include the visually dominant [OIII] emission, it is usually too faint by one to three magnitudes compared with the appearance to the eye.
- Diameters. Given in arcseconds, these are mostly from measures on various photographic plates. Because they have not been reduced to any uniform system, these values do not refer to any fixed brightness level of the nebulosity and hence should be considered approximate only. They usually refer to the bright, well-defined portion of the object, excluding extremely faint coronae visible on images reaching to very low light levels.
- Central star magnitudes. These are, for the very brightest stars, independent of any associated nebulosity. Although based on the most recent work, these magnitudes may, however, be subject to substantial error due to the brightness of the enveloping nebula. Brighter than about 14th magnitude, they are quite reliable to better than 0.1; fainter than this, the majority are good to within ±0.5 magnitude. Since few of these stars are brighter than magnitude 12.0 and since they are associated with nebulosity, they are most difficult to observe. Good results can be achieved at high telescopic magnifications, which have the effect of reducing the apparent brightness of the surrounding nebulosity while accentuating the central star.
- Alternate names. These are provided for all planetary nebulae which, of all deep-sky objects, suffer the most from an overabundance of alternate or secondary names. In the DSFG, as with *Uranometria 2000.0*, the name precedence is as follows: *New General Cata-*

logue (NGC), *Index Catalogue* (IC), and PN G from the *Strasbourgh/ESO Catalogue of Planetary Nebulae*. All planetaries have a PN G number assigned. Where an object has either an NGC or IC number, the alternate name will be its PN G designation. For objects with a PN G number as a primary name, the PK number is usually given as an alternate. An exhaustive cross-reference may be found in Hynes' *Planetary Nebulae*. Note also that some planetaries have Abell names and these should not be confused with similarly named galaxy clusters. Examples of these can be found in the notes for Charts 8 and 26 among others.

- Notes. These comments primarily point out two or more stars close by each planetary, giving their magnitudes, distance and direction from the object, to aid the observer in pinpointing the exact location of what is often an almost stellar target; or, on the other hand, to a planetary that might be quite large, faint and diffuse. The notes may also contain brief descriptions, where warranted, based on DSS images. Also, nonstellar objects whose names appear in bold type are not plotted on the charts, nor do they have data in the tables; however, direction and distance to these objects will be provided in the notes. Nonstellar objects whose names are in normal type will be found on the charts and will have an entry in the tables.

Abbreviations and Notation

For the most part, we have sought to avoid codes and abbreviations and wherever possible to use plain English descriptions. The following are the codes and abbreviations as used in the DSFG:

Colon(s) : denotes uncertainty
Question mark ? doubtful
Arcminutes ′ or ′.
Arcseconds ″
Directions N = north, S = south, E = west, W = west
Greater than >
Less than <
Approximately ≈
Greater than or equal to ≥
Plus or minus ±

Table 5
The Greek Alphabet

Alpha	α	Iota	ι	Rho	ρ
Beta	β	Kappa	κ	Sigma	σ
Gamma	γ	Lambda	λ	Tau	τ
Delta	δ	Mu	μ	Upsilon	υ
Epsilon	ε	Nu	ν	Phi	φ
Zeta	ζ	Xi	ξ	Chi	χ
Eta	η	Omicron	ο	Psi	ψ
Theta	θ	Pi	π	Omega	ω

Acknowledgments

Almost exactly 400 years ago, in 1603, a Bavarian lawyer named Johann Bayer (1572–1625) published the first *Uranometria*, which had as its "database" the observations of the Danish astronomer Tycho Brahe (1546–1601). The work you now have in your hands, in contrast, is the product of the knowledge and talents of a very large group of people, from which it has benefited in many ways—both seen and unseen. It comes at a point in time when cartographers can create a massive and reasonably uniform database, and then actually confirm the existence, size and position of the objects they plot—truly a revolution in celestial mapping.

In just the last few years there have been remarkable developments in technology which have enabled anyone with Internet access and suitable software to access and analyze the massive NASA/IPAC Extragalactic Database (NED) which is maintained by the Jet Propulsion Laboratory, California Institute of Technology, for NASA. While this alone would be a major advance over what was available just 14 years ago when the First Edition of *Uranometria 2000.0* was published, the availability of the Digitized Sky Survey created by the Space Telescope Science Institute, and operated for NASA by the Association of Universities for Research in Astronomy (AURA), has enabled us to personally verify the positions, orientations and sizes of objects—to an unprecedented level of accuracy—against the actual images upon which much of the data contained in NED was originally based.

Brian Skiff of Lowell Observatory has, from the beginning of this project, provided us with assistance on a wide variety of issues. Harold Corwin of IPAC/NED has also, over a number of years, provided data and valuable guidance—especially for galaxies and galaxy clusters. He and Steve Gottlieb were helpful in unraveling some of the tangled history of the *New General Catalog of Non-stellar Objects* and the two *Index Catalogs*.

Brent Archinal has graciously allowed us to use a subset of his Star Cluster catalog which will appear in *Star Clusters*, a book that he and Steven Hynes have in-press at Willmann-Bell.

We have also received valuable assistance from George Kepple, David Kriege, John Koester, Harold Suiter, Susan French, Glen Sanner, Larry Mitchell, Craig Crossen, Alister Ling, Richard Huziak, Jay LeBlanc, Kent Blackwell, and Leos Ondra.

While we have gone to extraordinary lengths to create the best possible large-scale atlas of the deep sky, we have no illusions—errors will be found. Whatever these errors turn out to be they are the responsibility of the authors and publisher. However, to our knowledge the First Edition of *Uranometria 2000.0* remains the only atlas ever published that has provided systematic errata which have been made widely available. That tradition will be maintained with this edition and, hopefully, those who come after us will not have to repeat them.

Bibliography

To reduce congestion on the atlas charts, we have chosen to abbreviate prefixes and remove leading zeros. In the

DSFG, however, we have used the full prefixes. In the listings below, the abbreviations used in the chart appear in brackets after the standard prefix.

BRIGHT NEBULAE

RA h m s	Dec ° ′ ″	Name	Dim ′ Maj x min	Type	BC	Color	Notes
20 26 42.0	+42 07 00	DWB 100-5-9	40 x 15	E	4-5	3-4	Very irregular in shape, mottled and of low surface brightness.
20 16 24.0	+41 49 00	IC 1318(b)	50 x 20	E	1-5	3-4	A large patch in the NNW part of the γ Cygni nebulae complex, about 2° distant from γ. It is elongated roughly N-S.
20 19 18.0	+40 44 00	IC 1318(c)	40 x 25	E	2-5	3-4	Very diffuse overall with four or five brighter condensations, the most prominent one about 30′ SE of Cr 419.
20 26 12.0	+40 30 00	IC 1318(d)	50 x 30	E	1-5	3-4	Centered approximately 1° E of γ Cygni. This and the bright patch 45′ SE are the brightest parts of the γ Cygni complex.
20 27 54.0	+40 00 00	IC 1318(e)	45 x 30	E	1-5	3-4	Centered 1.5° SE of γ Cygni. Comparable in size and brightness to the nebulosity 0.75° NW. A prominent dark lane separates them.
20 50 48.0	+44 21 00	IC 5067	25 x 10	E	1-5	3-4	Bright patch in the N part of the **Pelican Nebula**.
20 50 48.0	+42 31 00	IC 5068	40 x 30	E	2-5	3-4	
20 50 48.0	+44 11 00	IC 5070	60 x 50	E	3-5	3-4	The southern two thirds of the **Pelican Nebula**.
20 55 54.0	+47 25 00	IC 5076	9 x 7	R	1-5	1-4	The involved bright star is in the NE part of the nebula.
20 58 48.0	+44 20 00	NGC 7000	120 x 100	E	1-5	3-4	**North American Nebula**. Due to its faintness and large size, the shape giving rise to its nickname is very difficult to discern visually. The brightest portion is the area corresponding to Mexico.
20 33 54.0	+45 39 00	Sh2-112	13 x 13	E	2-5	3-4	
20 34 30.0	+46 52 00	Sh2-115	30 x 20	E	3-5	3-4	
20 24 18.0	+42 18 00	vdB 131	3 x 3	R	2-5	1-4	Nebula with a mag 9.1 star involved.
20 24 48.0	+42 23 00	vdB 132	4 x 4	R	2-5	1-4	Nebula with a star of mag 8.7 involved. A fainter, broad bridge of nebulosity, connects it to another nebula 7′ N. It is of similar size and surface brightness.

DARK NEBULAE

RA h m s	Dec ° ′ ″	Name	Dim ′ Maj x min	Opacity	Notes
21 32 08.5	+44 58 00	B 155	13 x 13	3	Round; indefinite; four small stars in a line crossing it E and W.
21 33 59.4	+45 35 00	B 156	8 x 8	3	Sharp pointed to N.
21 37 13.6	+43 24 40	B 158	3 x 3		Dark spot.
21 38 22.8	+43 14 00	B 159	25 x 25	5	Irregular partially vacant region.
20 09 30.8	+41 12 00	B 342	4.0 x 0.5	4	Small, dark marking; E and W.
20 13 26.0	+40 17 00	B 343	13 x 5	5	Elongated; NW and SE; sharpest at SE end.
20 16 12.2	+40 13 00	B 344	7 x 3	3	Dusky spot, like an arrowhead, pointed SW.
20 21 00.3	+46 34 00	B 345	15 x 2		Curved; convex to the E.
20 26 46.1	+43 45 00	B 346	10 x 4	3	Curved, black spot.
20 34 26.3	+42 06 00	B 348	60 x 3	3	Narrow; dusky; NE and SW.
20 47 24.2	+43 58 00	B 349	6 x 1		Small; curved; dusky.
20 49 06.7	+45 52 50	B 350	3 x 3	6	Small; round; dusky.
20 52 27.6	+47 24 00	B 351	3 x 25		Crooked, dusky lane, NE and SW.
20 57 10.8	+45 54 00	B 352	20 x 10	5	Large; black; sharply defined on SE side.
20 57 22.6	+45 29 00	B 353	12 x 6		Definite; dusky; N and S.
20 59 38.0	+43 11 00	B 355	5 x 5		Dark; definite; E and W lanes; like a letter V-the open end toward the E.
20 59 58.8	+46 41 00	B 356	24 x 24	5	Irregular; dusky.
21 05 40.6	+43 17 00	B 358	20 x 20		Diffuses to NE; a curve of stars along N edge.
21 12 45.8	+47 26 00	B 361	17 x 17	4	Round; irreg. extension to W for ½° ±.
21 23 57.8	+50 12 00	B 362	15 x 8	5	Elongated; NE and SW.
21 24 53.8	+48 56 00	B 363	40 x 15	3	Irregular; dusky; NE and SW.
20 24 48.0	+40 10 00	LDN 889	180 x 20	4	Wide lane E of γ Cygni.
20 56 48.0	+43 52 00	LDN 935	90 x 20	4	Wide lane separating the North America and Pelican nebulae.

BRIGHT NEBULAE

42

RA h m s	Dec ° ′ ″	Name	Dim ′ Maj x min	Type	BC	Color	Notes
04 03 24.0	+51 19 00	NGC 1491	25 x 25	E	1-5	3-4	Considerably smaller (about 4′) on blue photographs than on red. Visual observers may be able to detect two strong wisps forming a narrow V-shape (open end to NNE) in the nebula's brightest part. A star about 11th mag lies just SE of this area.
04 40 24.0	+50 27 00	NGC 1624	5 x 5	E	1-5	3-4	
05 27 18.0	+42 59 00	Sh2-224	20 x 3	SNR-E	5-5	4-4	An incomplete oval ring. The brightest part is a slightly convex crescent along the N circumference. This very narrow strip about 12′ long is convex toward a mag 8 star a short distance NW.

DARK NEBULAE

RA h m s	Dec ° ′ ″	Name	Dim ′ Maj x min	Opacity	Notes
04 31 56.0	+46 37 00	B 15	10 x 15	5	Elliptical.
04 32 26.0	+46 36 00	B 16		5	Very small; elongated N and S; close to SE edge of B15.
04 32 30.6	+46 31 00	B 17		5	Very small; elongated N and S; close to E edge of B15.
04 37 04.5	+50 59 00	B 20	60 x 60	2	In S part of larger, relatively vacant area.
04 52 04.1	+46 01 00	B 25	8 x 8	3	Irregularly round.

PLANETARY NEBULAE

OPEN CLUSTERS

RA h m s	Dec ° ′ ″	Name	Mag	Diam ′	No. ★	B ★	Type	Notes
04 06 41.0	+27 34 00	Do 14		10	18		cl	Few stars; small brightness range; no central concentration; detached.
03 47 29.0	+24 06 00	M 45	1.5	120	100	3.0	cl	**Pleiades**. Rich in stars; large brightness range; strong central concentration; detached; involved in nebulosity (S) Center star is Alcyone.

BRIGHT NEBULAE

RA h m s	Dec ° ′ ″	Name	Dim ′ Maj x min	Type	BC	Color	Notes
04 27 06.0	+26 07 00	Ced 33	5 x 2	R	4-5	3-4	Very faint and diffuse
04 27 18.0	+23 00 00	Ced 34	10 x 6	R	2-5	1-4	
03 46 18.0	+23 56 00	IC 349	26 x 26	R	1-5	1-4	Small knot in **vdB 22**. A small patch of nebulosity about 35′ south-southeast the star Merope (23 Tauri) in the Pleiades cluster.
03 55 00.0	+25 29 00	IC 353	180 x 30	R	3-5	1-4	(see IC 1995).
03 50 18.0	+25 35 00	IC 1995	135 x 135	R	3-5	1-4	A part of the larger nebula known as **LBN 774** which includes IC 353. This section, the E part of LBN 774, is more filamentary in structure than IC 353.
04 40 00.0	+25 44 00	IC 2087	4 x 4	R	3-5	3-4	Faint and diffuse; in a starless field. This object is also catalogued as Barnard 22.
03 45 48.0	+24 22 00	NGC 1432	26 x 26	R	2-5	1-4	= **vdB 21**. Brighter part of nebulosity surrounding the star Maia (20 Tauri) in the Pleiades cluster.
03 46 06.0	+23 47 00	NGC 1435	30 x 30	R	1-5	1-4	**Tempel's Nebula**, **Merope Nebula**. Condensation of nebulosity S of and semi-detached (in shorter exposures) from IC 349 which is a small knot in **vdB 22**.
04 21 48.0	+19 32 00	NGC 1554/55	1 x 1	R	2-5	3-4	**Hind's Variable Nebula**. Involved with the irregular variable star T Tauri. NGC 1554 lies 0′.75 W of the star but according to early observers it was SW of T Tauri. A much smaller nebulosity (apparently NGC 1555) surrounds the star itself. NGC 1555 also known as **Struveis Lost Nebula**.
03 28 18.0	+29 48 00	vdB 16	4.5 x 4.5	R	3-5	2-4	Nebulosity with a mag 9.1 star involved.
03 44 54.0	+24 07 00	vdB 20	11 x 11	R	3-5	1-4	Nebulosity surrounding the star Electra (17 Tauri) in the Pleiades cluster.
03 47 30.0	+24 06 00	vdB 23	17 x 17	R	3-5	1-4	Nebulosity surrounding the star Alcyone (η) (25 Tauri) in the Pleiades cluster.

DARK NEBULAE

RA h m s	Dec ° ′ ″	Name	Dim ′ Maj x min	Opacity	Notes
04 17 25.0	+28 34 00	B 7		5	Large, irregular, with brighter condensation (B10) in SE part.
04 18 41.2	+28 17 00	B 10	8 x 8	5	The brightest part of B7.
04 39 59.0	+25 45 00	B 14	3 x 3		Very small, bright nebula.
04 31 13.3	+24 21 00	B 18	60 x 60	5	Group of dark spots.
04 33 39.9	+26 16 00	B 19	60 x 60		Large; indefinite.
04 38 39.9	+26 03 00	B 22	120 x 120	4	**Taurus Dark Cloud**. Irregular; unequally dark; extended SE and NW.
04 40 33.4	+29 53 00	B 23	5 x 5	5	Sharply pointed to the SE.
04 42 53.3	+29 44 00	B 24	8 x 8	5	Sharply pointed to the S.
04 04 35.4	+26 21 00	B 207			Small black spot, elongated nearly N and S.
04 11 32.9	+25 10 00	B 208			Darker spot in dark lane.
04 12 23.3	+28 20 00	B 209			Center of a broad extension from B7, toward the W.

BRIGHT NEBULAE

RA h m s	Dec °	Name	Dim ′ Maj x min	Type	BC	Color	Notes
05 45 18.0	+09 04 00	Ced 59	3 x 2	E+R	1-5	3-4	
06 31 00.0	+10 27 00	IC 446	5 x 4	R	3-5	1-4	Nebula with a faint central star involved. At the N edge of dark nebula LDN 1607 (not plotted).
06 32 42.0	+07 19 00	IC 448	15 x 10	R	3-5	1-4	
06 13 06.0	+17 58 00	IC 2162	3 x 3	E	2-5	3-4	Similar in size, shape and surface brightness to Sh2-257.
06 31 12.0	+09 54 00	IC 2169	25 x 20	R	3-5	1-4	There is a relatively large absorption patch in the NE sector.
06 32 18.0	+05 03 00	NGC 2237-9, 46	80 x 60	E	1-5	3-4	**Rosette Nebula**. A large, bright and mottled nebulosity. This roundish nebula is involved in a sparse cluster of naked eye stars. The NW sector contains many tiny absorption patches.
06 32 42.0	+10 10 00	NGC 2245	5 x 4	R	1-5	2-4	Comet-shaped nebula with a mag 11 star involved.
06 33 12.0	+10 20 00	NGC 2247	6 x 6	R	1-5	2-4	A mag 8.5 star involved in the N part.
06 39 12.0	+08 44 00	NGC 2261	3.5 x 1.5	E+R	1-5	2-4	**Hubble's Variable Nebula**. Fan-shaped object with the apex at the S end.
06 12 48.0	+17 58 00	Sh2-257	3 x 3	E	2-5	3-4	This roundish nebula is quite bright and well defined.
06 08 54.0	+15 49 00	Sh2-261	30 x 25	E	3-5	3-4	Very mottled, roundish nebulosity. The central region is of lower surface brightness, the southern 1/3 brightest.
05 35 00.0	+10 00 00	Sh2-264	270 x 240	E	4-5	3-4	
05 21 42.0	+08 27 00	vdB 38	30 x 25	E+R	3-5	2-4	A mag 5.8 star on NE edge of irregular nebula.

DARK NEBULAE

RA h m s	Dec ° ′ ″	Name	Dim ′ Maj x min	Opacity	Notes
05 30 16.5	+12 46 00	B 30	67 x 67	4	Large dark area with few stars.
05 32 01.5	+12 46 00	B 31	30 x 30	4	Extended NE and SW; the E and darkest part of B30.
05 32 08.5	+12 26 00	B 32		3	Dark projection from S end of B31 to the E.
05 45 30.7	+09 03 00	B 35	20 x 10	2	Elongated E and W with an extension SE; three small stars N of it.
05 49 45.9	+07 25 00	B 36	120 x 120	4	Irregular narrow dark lane NE and SW. The NE end connects brokenly with B35.
06 32 55.0	+10 29 00	B 37	180 x 150	4	Irregular, semi-vacant region.
06 33 41.8	+11 05 00	B 38	60 x 60	4	Irregular vacancy. This seems to refer to a portion of B37.
06 38 02.5	+10 20 00	B 39		5	Small, sharply defined, elongated spot in the nebulosity NW of 15 Monocerotis.
05 21 28.1	+08 20 00	B 223	8 x 8		Fan-shaped nebula.
05 23 54.9	+10 37 00	B 224	20 x 20		Indefinite.
05 28 58.0	+11 36 00	B 225	35 x 5		South end of extension running S from B30.

BRIGHT NEBULAE

RA h m s	Dec ° ′ ″	Name	Dim ′ Maj x min	Type	BC	Color	Notes
05 33 24.0	−00 37 00	IC 423	6 x 4	R	2-5	1-4	Shaped like a comet-head. It is extended roughly N-S and fans out slightly at the N end. On blue photos the interior is darker, especially in the S part.
05 33 36.0	−00 25 00	IC 424	2 x 2	R	2-5	1-4	Two faint stars (aligned E-W, sep. 20″) involved in the S part.
05 36 48.0	−00 15 00	IC 426	7 x 7	R	2-5	1-4	Very irregular in shape with an extension, about 3′ x 1′, off the SE sector.
05 40 18.0	−01 27 00	IC 431	5 x 3	R	1-5	1-4	
05 40 54.0	−01 29 00	IC 432	8 x 4	R	1-5	1-4	
05 41 00.0	−02 24 00	IC 434	60 x 10	E	1-5	3-4	
05 43 00.0	−02 19 00	IC 435	4 x 3	R	1-5		
05 35 06.0	−04 44 00	NGC 1973	5 x 5	E+R	1-5	1-4	Nebulosity associated with the variable star KX Orionis.
05 35 24.0	−04 41 00	NGC 1975	10 x 5	E+R	1-5	1-4	
05 35 24.0	−05 27 00	NGC 1976	65 x 60	E+R	1-5	3-4	= **M 42**, **Orion Nebula**. Very bright and mottled. This galactic nebula is visible to the naked eye.
05 35 30.0	−04 52 00	NGC 1977	20 x 10	E+R	1-5	1-4	Associated with a sparse group of about a dozen stars; nebulosity brightest in the S part.
05 35 24.0	−05 54 00	NGC 1980	14 x 14	E	3-5	4-4	The southernmost semi-detached part of the **Orion Nebula**.
05 35 36.0	−05 16 00	NGC 1982	20 x 15	E+R	1-5	3-4	= **M 43**. Bright nebulosity with a mag 7 star involved; part of **M 42**, **Orion Nebula** and separated from it by a dark lane.
05 41 36.0	−02 16 00	NGC 2023	10 x 10	E+R	1-5	1-4	
05 41 54.0	−01 51 00	NGC 2024	30 x 30	E	2-5	3-4	**The Flame**. This nebula is approximately bisected by a dark lane 3′ wide, aligned roughly N-S; E section of nebula slightly larger.
05 46 18.0	+00 00 00	NGC 2064	1.5 x 1.0	R	2-5	2-4	A small, relatively bright patch; extended roughly N-S.
05 46 30.0	+00 06 00	NGC 2067	8 x 3	R	2-5	2-4	This nebula is considerably lower in surface brightness than nearby M 78. It is a diffuse patch 3′ across with a narrow extension SSW, nearly to NGC 2064.
05 46 42.0	+00 03 00	NGC 2068	8 x 6	R	1-5	2-4	= **M 78**. Brightest and largest in a group of four nebulae with NGCs 2064, 2067 and 2071. This slightly oval nebula has two 10th mag stars involved.
05 47 12.0	+00 18 00	NGC 2071	7 x 5	R	2-5	2-4	Second brightest in a group of four nebulae with NGCs 2064, 2067 and 2071. There is a 10th mag star involved and another field star off the NW edge.
06 32 18.0	+05 03 00	NGC 2237-9, 46	80 x 60	E	1-5	3-4	**Rosette Nebula**. A large, bright and mottled nebulosity. This roundish nebula is involved in a sparse cluster of naked eye stars. The NW sector contains many tiny absorption patches.
05 48 00.0	+01 00 00	Sh2-276	600 x 30	E	3-5	3-4	**Barnard's Loop**. The NE section is its brightest part.
05 20 00.0	−05 40 00	Sh2-278	25 x 20	E	4-5	3-4	
06 38 00.0	+01 31 00	Sh2-282	25 x 10	E	3-5	3-4	Nebulosity with several stars liberally sprinkled throughout.
05 39 12.0	+04 10 00	vdB 49	8 x 3	R	3-5	1-4
